

Nuclear Fallout from the Nevada Test Site 1951-1970: New Mexico

This series of books consists of county-by-county estimates of radioactive fallout from specific nuclear devices detonated at the Nevada Test Site, 1951-1970. Fallout is derived from I-131 fallout estimates given in terms of geometric mean and geometric standard deviation. Averages (arithmetic means) were calculated for these ranges and the single values were listed for each county in terms of nano-Curies per square meter, the name of the device that produced the fallout, and the day the fallout event occurred. For example: County: AZ Coconino-1 (first subdivision of Coconino County, Arizona) nCi/sq meter: 46410.5 Nuclear Test/Day: TS6-1 (first day after the sixth nuclear test in the Tumbler-Snapper series) Date: 25 May-1952 The data was based on Iodine-131 values found in the National Cancer Institutes 1997 report: Estimated Exposures and Thyroid Doses Received by The American People from Iodine-131 in Fallout Following Nevada Atmospheric Nuclear Bomb Tests as well as documents by Harry Hicks of Lawrence Livermore National Laboratory: Results of Calculations of External Gamma Radiation Exposure Rates from Fallout and The Related Radionuclide Compositions.
