

My back-yard zoo, a course of natural history

This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1886 Excerpt: ...and which is known by the name of feathers. Feathers are restricted to the bird tribes. Many birds have hairs like those of most mammals; they have scales on their hind limbs, like those of the manis, and some of them have spines like those of the porcupine or hedgehog. But, as far as is known, no mammal ever possessed feathers, and therefore the name of the feathered tribes is a very appropriate one. Yet feathers and hair are precisely alike in material, feathers being horny secretions of the skin, and, in fact, nothing but highly developed hairs. So are the hollow horns of the oxen, sheep, and antelopes, and other ruminants. So is the solid horn which projects from the nose of the rhinoceros. So are the hoofs which defend the feet of many animals, and the nails which grow at the ends of our fingers and toes. So are scales and teeth. It seems strange that the soft tresses of a lady should be identical in material with the bristles of a pig, or the horn of a cow. But it is so, and now and then some very curious proofs of their identity are found. There is in the Waterton Museum, now at Ushaw College, the head of a sheep with a large horn growing from the tip of one ear. The hairs have become fused together, and so have produced horn. The first use of the feathers is to preserve the heat of the bird: and for this purpose they are peculiarly fitted. Their structure enables them to entangle a large amount of air among their fibres, or hair barbules as they are called, and, as air is a bad conductor of heat, the warmth of the body is retained. The second object for which feathers are intended is flight. Only the feathers that grow on the fore limbs are used for this purpose, and they are much stiffer than those that clothe the body. All
